This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

GEORGE A. WENTWORTH AND GEORGE A. HILL,
in the Office of the Librarian of Congress, at Washington.

PREFACE.

THE objects to be attained in the study of Arithmetic are mental discipline and practical mastery of the subject. These objects are best secured by solving problems that are progressive in character and grouped under a few general heads.

This collection of problems is not intended to supplant text-books in Arithmetic, but to supplement them. A great number and variety of examples are given under each head, for the express purpose of enabling a teacher *to select* such as are specially adapted to the needs of his classes. The examples are, in the main, practical; that is, similar to examples that occur in the ordinary affairs of life; and many of them give accurate and interesting information.

The authors will be glad to receive information in regard to errors, and suggestions for improving the work.

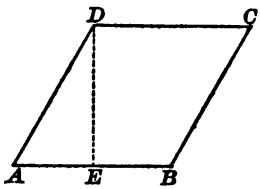
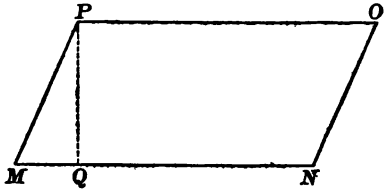
A **Rhombus** is a quadrilateral having *all* its sides equal, but its angles not right angles.

ABCD is a rhombus; *AB* is called its *base*, and the line *DE*, drawn from *D* perpendicular to *AB*, is called its *altitude*.





A **Rhomboid** is a quadrilateral having its *opposite* sides equal, and its angles not right angles.

MNOP is a rhomboid; *MN* is its *base* or *length*; *PQ* drawn perpendicular to *MN* is its *altitude*.

A **Parallelogram** is a quadrilateral having its opposite sides parallel. The square, the rectangle, the rhombus, and the rhomboid are all of them parallelograms.

The opposite sides of a parallelogram are equal, and the opposite angles are also equal.

The sum of the four angles of any parallelogram is equal to four right angles, or 360°.

Area of any parallelogram = base × altitude.

138. Base 18 in., altitude 13 in.

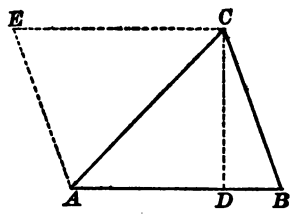
A **Triangle** is a plane figure bounded by three straight lines. The figure ABC is a triangle.

A triangle, ABC, has three sides, AB, BC, AC, and three angles, ABC, BCA, CAB.

The side AB is called the *base*, the opposite corner C the *vertex*, and the perpendicular CD, drawn from C to AB, the *altitude*. Either one of the other sides might be taken as the base. If AC is taken as the base, the opposite corner B would be the vertex, and the perpendicular drawn from B to AC would be the altitude.



The sum of the angles of a triangle is equal to two right angles, or 180°.

Any triangle, ABC, is equal in area to one-half of a parallelogram, $ABCE$, having the same base AB as that of the triangle, and also the same altitude CD; therefore,

Area of a triangle $= \frac{1}{2}$ (*base* $\times$ *altitude*).

If the three sides of a triangle are given, the area is found as follows: From the half-sum of the sides subtract each side separately. Multiply the half-sum and the three remainders together. The square root of the product is the area of the triangle.

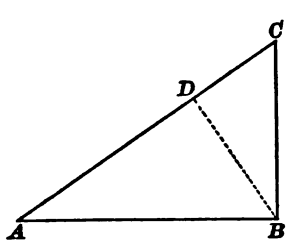
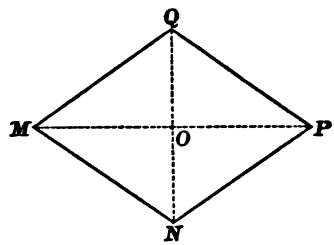
A **Right Triangle** is a triangle having a right angle.

In the right triangle ABC, the right angle is at B; the sides AB, BC, which form the right angle, are called the *legs*, and the side AC is called the *hypotenuse*.

The sum of the two acute angles of a right triangle is equal to one right angle, or 90°.

If one of the acute angles is equal to 30°, the opposite side is equal to half the hypotenuse.





The sum of the squares upon the two legs of a right triangle is equal to the square upon the hypotenuse; or,

$$\overline{AB}^2 + \overline{BC}^2 = \overline{AC}^2.$$

If one of the legs, as AB, be taken for the base, then the other leg BC will be the altitude; therefore,

Area of a right triangle = half the product of its legs.

The diagonals of a rhombus $MNPQ$ bisect each other at right angles, and divide the rhombus into four equal right triangles; hence

Area of a rhombus = half the product of its diagonals.

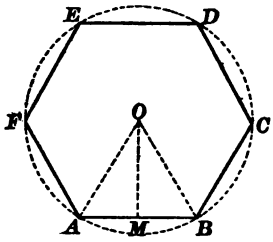
A **Regular Polygon** is a polygon having all its sides equal and all its angles also equal.



There is in every regular polygon a point equidistant from the corners and also equidistant from the sides; this point is called the *centre*.

The distance from the centre to any corner is called the *radius*, and the distance from the centre to any side is called the *apothem*.

The figure *ABCDEF* is a regular hexagon; *O* is the centre, *OA* the radius, *OM* the apothem.

The radii of a regular polygon divide the figure into equal isosceles triangles; hence it follows that,

Area of a regular polygon = ½ × *perimeter* × *apothem*.

The radius of a regular hexagon is equal to one side, and the radius of an equilateral triangle is equal to twice the apothem.

The apothem of a regular polygon bears a constant ratio (usually irrational) to one side; for most purposes the following values are sufficiently accurate:

No. of sides.	*Apothem.*	*No. of sides.*	*Apothem.*
3	one side × 0.2877.	7	one side × 1.0382.
4	one side × 0.5000.	8	one side × 1.0071.

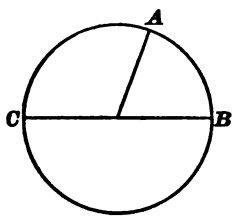
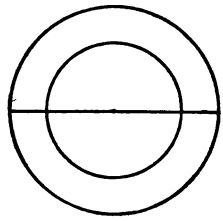
A Circle is a plane figure bounded by a curved line called a *circumference*, every point of which is equally distant from a point within called the *centre*. A line drawn from the centre to the circumference is called a *radius*, and a line drawn through the centre and limited by the circumference is called a *diameter*; therefore a diameter is equal in length to two radii.





The circumferences of two circles have the same ratio to each other as their radii, or as their diameters. Thus, if the radius of a circle be doubled, the circumference will also be doubled; or, if the diameter be trebled, the circumference will also be trebled; and so on. It follows that the ratio of the circumference of a circle to its diameter is the same for all circles. The exact value of this ratio cannot be expressed by numbers, but the value near enough for most practical purposes is $\frac{22}{7}$.

Concentric circles are circles having the same centre.

Circumference of a circle $= \frac{44}{7} \times$ *radius.*

Radius of a circle $= \frac{7}{44} \times$ *circumference.*

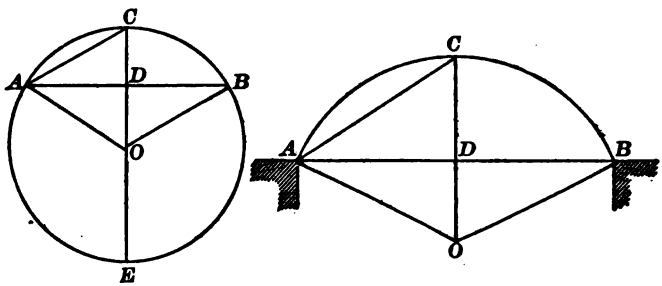
An Arc is any part of a circumference, as ACB.

A **Chord** is a straight line joining the ends of an arc. Thus, AB is the chord of the arc ACB.

The diameter COE, drawn through the middle point D of the chord AB, bisects also the arc ACB, and is perpendicular to the chord; AD is half the chord AB, and AC is the chord of half the arc ACB; CD is called the *height* of the arc ACB. It may be proved that AC is a mean proportional between CD and CE, and that AD is a mean proportional between CD and DE; in other words,

$$\overline{AC}^2 = CD \times CE; \text{ and } \overline{AD}^2 = CD \times DE.$$



The arch of a bridge often has the form of a circular arc; in this case, AB is the *span*, CD the *height* or *rise* above the piers.

The angle AOB is the *angle at the centre* subtended by the arc ACB. Every circumference is regarded as composed of 360 equal arcs, called *degrees;* and an arc ACB contains the same number of degrees, minutes, and seconds as the angle at the centre AOB; also,

$$\frac{\textit{Length of an arc}}{\textit{Circumference}} = \frac{\textit{Number of degrees in arc}}{360°}.$$

A **Sector** is a portion of a circle bounded by two radii and the arc contained between them. The figure $AOBC$ is a sector; the angle AOB is the angle of this sector.

A **Segment** is a portion of a circle bounded by an arc and its chord. The figure $ADBC$ is a segment.

Every diameter divides a circle into two equal parts called *semicircles;* and two diameters perpendicular to each other divide a circle into four equal parts called *quadrants.*

The area of a sector has the same ratio to the area of the entire circle that the arc of the sector has to the entire circumference; hence it follows that:

$$\frac{\text{Area of sector}}{\text{Area of circle}} = \frac{\text{Angle of sector}}{360°}.$$

The area of the segment $ADBC$ is found by subtracting that of the triangle AOB from that of the sector $AOBC$.

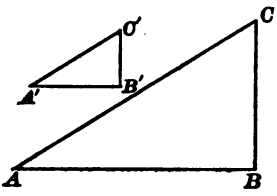
Two polygons are similar if they are equiangular with respect to each other, and have their homologous sides proportional. The homologous sides are the sides opposite the equal angles. Thus, the



triangles ABC, $A'B'C'$ are similar triangles, and

$$AB : A'B' = BC : B'C';$$
$$AB : A'B' = AC : A'C';$$
$$BC : B'C' = AC : A'C';$$

All regular polygons having the same number of sides are similar to each other.

The areas of two similar figures are proportional to the *squares* of any two homologous sides.

The radii of two regular polygons of the same number of sides are proportional to their sides; and the same is true of their apothems.

The entire surface of a rectangular parallelopiped is the sum of the six rectangles of which it is composed, and the

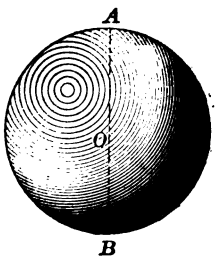
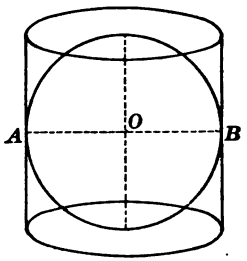
A **Sphere** is a solid bounded by a curved surface all points of which are equally distant from a point within called the *centre*.

A straight line drawn from the centre to the surface is called a *radius*, and a straight line drawn through the centre and terminated each way by the surface is called a *diameter*.





The *circumscribing* cylinder of a sphere is a cylinder whose height and the diameter of whose base are both equal to the diameter of the sphere (see Fig.).

It can be proved that the surface of a sphere is just equal to two-thirds the *lateral* surface of the circumscribing cylinder, and that the volume of a sphere is just equal to two-thirds the volume of the circumscribing cylinder. Hence it follows that (assuming π to be equal to $\frac{22}{7}$),

$$\textit{Surface of a sphere} = \tfrac{22}{7} \times (\textit{radius})^2.$$

$$\textit{Volume of a sphere} = \tfrac{88}{21} \times (\textit{radius})^3.$$
